Stampa 3D dei Dispositivi medici: evoluzione normativa e buone prassi

Sandro Storelli, Coordinatore Osservatorio Biomedicale Veneto

Orientamenti e supporti

I due migliori orientamenti, come mostrato nella letteratura, sono 0° occlusali in basso e 60° linguali in basso. Tuttavia, notate che la densità di sostegno ha ancora enormi quantità di supporti sull'occlusale. vedo gente provare i 60° e non appoggia la mossa occlusale-cattiva

SprintRay

3D PRINTED CERAMIC CROWN

SCIENTIFIC STUDIES SUMMARY

SprintRay Ceramic Crown has undergone the following studies:

- Fracture Load and Abrasion Resistance
- Occlusal Wall Thickness Effect on Fracture Load
- Chewing Simulation Abrasion Resistance
- Bonding Strength with Luting Composite
- Shear Bond Strength Luting Workflow Comparison

CONTENTS

Four crown replicates were made for each experimental group and cemented with Panavia SA to 3D printed stumps designed to mimic a clinical prep scan. The crowns were subjected to thermal cycling and antagonist loading with steatite material which mimics the mechanical properties of natural enamel. The chewing simulation comprised 400,000 cycles with a vertically applied load of 50N, with thermal cycling of 10,700 cycles alternating between 5°C and 55°C.

The fracture load was evaluated using a universal testing machine. The specimens were loaded with a 5mm diameter steel antagonist in the middle of the occlusal surface, with load applied until failure (tested in accordance with DIN EN ISO 7500-1). Failure load was evaluated with and without chewing simulation to determine the effect of this simulated wear on functional mechanical performance. Statistical analysis was performed using two-factor ANOVA and post-hoc Tukey pairwise comparison.
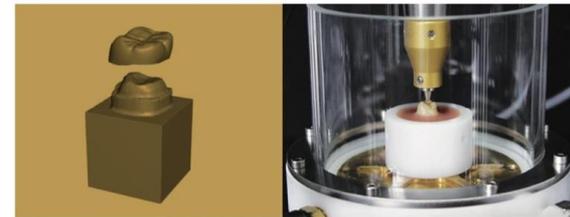

Figure 1:
3D design used for crowns and cemented stumps (left) and testing apparatus (right).
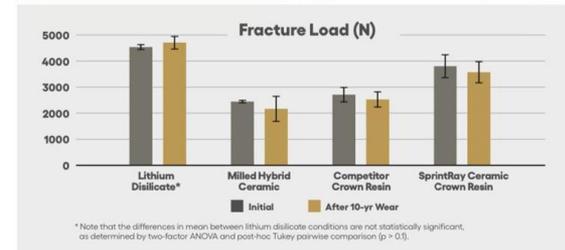

Figure 2:
Fracture load of cemented crowns before and after chewing simulation demonstrated significant differences between all materials tested ($p < 0.01$).

Fracture Load (N)

*Note that the differences in mean between lithium disilicate conditions are not statistically significant, as determined by two-factor ANOVA and post-hoc Tukey pairwise comparison ($p > 0.1$).

Results

The fracture load of SprintRay Ceramic Crown averaged 3815 N prior to the chewing simulation, and there was no significant change in this value after the simulation which indicates no detectable material fatigue ($p > 0.1$). The 3D printed competitor crown resin had a significantly lower fracture load of 2693 N ($p < 0.01$).

The milled lithium disilicate and hybrid ceramic materials had average fracture loads of 4560 N and 2460 N, respectively. Milled lithium disilicate had a greater fracture load compared to SprintRay Ceramic Crown, while milled hybrid ceramic had a significantly lower fracture load. For all materials, the differences in fracture load following the chewing simulation were not statistically significant ($p > 0.1$).[5]
